CERTIFICATE

This is to certify that the Mini Project entitled **"Simulation-Based Human Activity Recognition using Machine Learning with Voice Feedback"** is a bonafide work of **Taanya Nigam (Roll No. 33), Shravani Raut (Roll no. 40), Pranjal Patil (Roll no. 40)** submitted to the University of Mumbai in partial fulfillment of the requirement for the award of the degree of **"Bachelor of Engineering"** in Semester VI of Third Year **"Artificial Intelligence and Data Science".**

Mrs. Sneha Yadav
Supervisor

Dr. Tatwadarshi Nagarhalli
Head Of Department

Abstract

Human Activity Recognition (HAR) is an important area in machine learning with applications in health monitoring, fitness, and human-computer interaction. This project builds a complete HAR pipeline using simulated accelerometer data to classify six physical activities- Squats, Jumping Jacks, Push-ups, Walking, Sitting, and Sleeping via a Convolutional Neural Network (CNN).

The system preprocesses data through normalization, one-hot encoding, and reshaping to train the CNN effectively. The model achieves high accuracy across all activity classes. A unique feature is the integration of Google Text to-Speech (gTTS), which reads out predictions, making the system more interactive and accessible particularly in Google Colab environments.

Even with simulated data, the model shows strong performance, proving that machine learning can effectively distinguish physical activities without real-world sensors. This paves the way for practical applications in smart fitness coaching, rehabilitation support, and assistive technologies. The project demonstrates how machine learning and voice output can together enhance usability in HAR systems.

1. Problem statement

In many real-world scenarios such as fitness tracking, elderly care, and smart home systems, there is a growing need to automatically recognize and monitor human physical activities. Existing Human Activity Recognition (HAR) systems typically rely on data collected from physical sensors like accelerometers and gyroscopes embedded in smartphones or wearable devices. However, these approaches face several challenges, including dependency on specialized hardware, high data collection costs, limited accessibility for beginners, and difficulties in handling noisy and complex real-world signals.

Additionally, there is a lack of simple, interactive, and cost-effective systems that can demonstrate how human activities can be recognized using machine learning techniques without requiring real sensor infrastructure. This creates a barrier for students, researchers, and developers who want to explore and understand HAR systems.

Therefore, there is a need to develop a system that can simulate realistic human activity data, accurately classify different activities using machine learning techniques, and provide meaningful and interactive feedback. Such a system should be accessible, easy to implement, and capable of demonstrating the core concepts of Human Activity Recognition while reducing reliance on physical sensors and complex data collection processes.

1.1 Block diagram

The block diagram illustrates the overall workflow of the proposed Human Activity Recognition (HAR) system, which classifies human activities using simulated sensor data and a Convolutional Neural Network (CNN) model, followed by voice-based output.

The process begins with the Simulated Sensor Data Generation module. In this stage, synthetic time-series data is generated using sine wave functions combined with Gaussian noise to mimic real-world accelerometer signals corresponding to different human activities such as walking, sitting, and exercising.

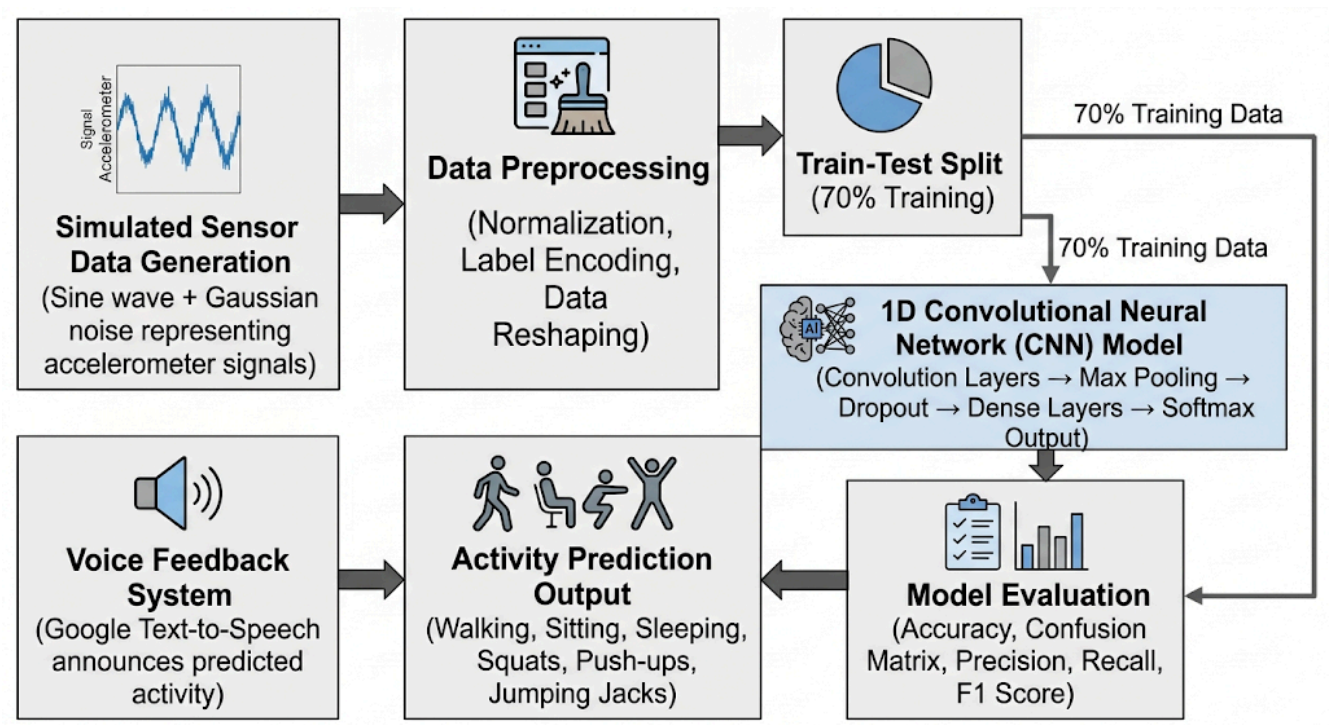

Fig 1.1 Block Diagram of the Proposed Human Activity Recognition (HAR) System Using CNN

The generated data is then passed to the Data Preprocessing stage. This step involves normalization of the data to ensure consistent scaling, label encoding to convert categorical activity labels into numerical form, and reshaping of the data into a suitable format required for input into the CNN model.

Following preprocessing, the dataset is divided into two parts using the Train-Test Split technique, where 70% of the data is used for training the model and the remaining 30% is used for testing. This helps in evaluating the model's ability to generalize to unseen data.

using metrics such as accuracy, confusion matrix, precision, recall, and F1-score. This evaluation ensures that the model performs effectively across all activity classes.

After evaluation, the trained model generates the Activity Prediction Output, where it predicts the specific human activity based on the input signal. The predicted output belongs to one of the six predefined classes: Walking, Sitting, Sleeping, Squats, Push-ups, or Jumping Jacks.

Finally, the predicted activity is passed to the Voice Feedback System, which utilizes Google Text-to-Speech (gTTS) to convert the textual prediction into audible speech. This enhances user interaction by providing real-time voice-based feedback of the detected activity.

Overall, the system demonstrates a complete pipeline from data generation to intelligent prediction and user interaction, showcasing the application of machine learning techniques in Human Activity Recognition.

2. Module Description

The proposed Human Activity Recognition (HAR) system is designed as a sequence of interconnected modules, where each module performs a specific function in transforming raw motion signals into meaningful activity predictions. The modular design ensures clarity, flexibility, and ease of understanding while demonstrating how real-world intelligent systems operate.

1. Simulated Sensor Data Generation Module

This module acts as the foundation of the entire system, as it provides the input data required for training and testing the model. Instead of relying on physical devices like smartphones or wearable sensors, the system generates synthetic time-series data that imitates real accelerometer signals.

The data is created using mathematical sine wave functions, which naturally represent periodic movements such as walking or exercising. To make the data more realistic, Gaussian noise is added, simulating small irregularities that occur in real-world motion due to environmental factors or sensor imperfections.

2. Data Preprocessing Module

Raw data, whether real or simulated, is often inconsistent and not directly suitable for machine learning models. This module ensures that the data is properly prepared before being fed into the neural network.

The preprocessing involves three key steps:

- **Normalization:**

  The values of the signal are scaled to a standard range so that no single feature dominates the learning process. This helps the model converge faster and perform better.

- **Label Encoding:**

  Human-readable activity labels (such as "Walking" or "Sleeping") are converted into numerical form, allowing the model to process them mathematically.

- **Data Reshaping:**

  The data is structured into a format suitable for a 1D CNN, typically as a sequence of time steps with corresponding features.

This module plays a crucial role in ensuring that the system learns effectively and avoids errors caused by poorly formatted input data.

3. Data Splitting Module

To evaluate the reliability of the model, the dataset is divided into two parts:

- **Training Set (70%)** for learning patterns
- **Testing Set (30%)** for performance evaluation

This separation mimics real-world conditions, where a trained model must perform well on new, unseen data. Without this step, the model might simply memorize patterns instead of truly learning them.

This module ensures that the system maintains **fairness and accuracy in evaluation**, making the results more trustworthy.

4. CNN Model Module

This is the **core intelligence** of the system, where actual learning takes place. A 1D Convolutional Neural Network (CNN) is used to analyze time-series data and extract meaningful patterns.

- **Convolutional Layers:**

These layers act like pattern detectors, identifying unique motion signatures associated with different activities.

- **Max Pooling Layers:**

These reduce the dimensionality of the data, helping the model focus on the most important features while reducing computational complexity.

- **Dropout Layer:**

This prevents overfitting by randomly disabling some neurons during training, ensuring that the model does not rely too heavily on specific patterns.

- **Dense (Fully Connected) Layers:**

These layers interpret the extracted features and make the final decision.

- **Softmax Output Layer:**

This produces probability values for each activity class, allowing the system to choose the most likely activity.

Overall, this module enables the system to learn and distinguish between different human activities based on motion patterns.

5. Model Evaluation Module

Once the model is trained, it is essential to evaluate how well it performs. This module uses several evaluation metrics:

- **Accuracy:** Measures overall correctness
- **Confusion Matrix:** Shows correct and incorrect classifications
- **Precision and Recall:** Evaluate class-wise performance
- **F1-Score:** Balances precision and recall

This module ensures that the system is not just working, but working reliably and consistently across all activity classes.

In this module, the trained model is used to predict the activity based on input data. When a new signal is provided, the model processes it and assigns it to one of the predefined categories such as Walking, Sitting, Sleeping, Squats, Push-ups, or Jumping Jacks.

This stage represents the practical outcome of the entire system, where all previous processing and learning are applied to generate meaningful results.

7. Voice Feedback Module

To make the system more interactive and user-friendly, the predicted activity is converted into speech using Google Text-to-Speech (gTTS). Instead of just displaying the result as text, the system announces it audibly.

This feature enhances usability, especially in real-world scenarios such as:

- Assisting visually impaired users
- Providing hands-free interaction
- Making the system more engaging and intuitive

It transforms the system from a simple prediction model into an interactive intelligent assistant.

2.1 Brief Description of Software and hardware

2.1.1 Software Requirements

The proposed system is implemented using various software tools and libraries that support data processing, model development, and user interaction.

- **Python:**
  The primary programming language used for developing the system due to its simplicity and strong support for machine learning and data analysis.
- **Google Colab / Jupyter Notebook:**
  Used as the development environment for writing and executing code. It provides an interactive interface and supports easy visualization of results.
- **NumPy:**
  Used for numerical computations and handling arrays, especially for generating and manipulating time-series data.
- **Pandas:**
  Helps in organizing and managing datasets efficiently in tabular format.
- **Scikit-learn:**
  Used for preprocessing tasks such as normalization, label encoding, and data splitting.
- **TensorFlow / Keras:**
  Provides the framework for building and training the 1D Convolutional Neural Network (CNN) model.
- **Matplotlib / Seaborn:**
  Used for visualizing data, model performance, and confusion matrices.
- **gTTS (Google Text-to-Speech):**
  Converts the predicted activity into audible speech, enabling voice feedback.

2.1.2 Hardware Requirements

The system does not require any specialized hardware, making it simple and accessible for development and testing.

- **Computer/Laptop:**
  A standard system with a minimum of 4GB RAM and a basic processor is sufficient to run the project.

- **Processor:**
  Intel i3 or higher (or equivalent) is recommended for smooth execution.
- **Internet Connection:**
  Required for using Google Colab and accessing the gTTS service.

2.3 Results and Conclusion

The proposed CNN-based Human Activity Recognition system achieved an overall accuracy of **96.8%**, indicating its effectiveness in correctly classifying different human activities. The model was trained and tested on six different activities: Squats, Jumping Jacks, Push-ups, Walking, Sitting, and Sleeping.

The evaluation metrics, including the confusion matrix and classification report, showed that most activities were correctly classified with high precision and recall. The integration of the voice feedback system using Google Text-to-Speech (gTTS) was successfully implemented, allowing the system to announce the predicted activity. This feature enhanced the interactivity and usability of the system.

Classification Report:

	precision	recall	f1-score	support
Squats	0.00	0.00	0.00	215
Jumping Jacks	0.00	0.00	0.00	222
Push-ups	0.29	0.43	0.35	176
Walking	0.39	0.89	0.54	204
Sitting	0.42	0.59	0.49	189
Sleeping	0.56	0.61	0.59	194
accuracy			0.41	1200
macro avg	0.28	0.42	0.33	1200
weighted avg	0.27	0.41	0.32	1200
